Overview

- There are many **graph databases** such as Neo4j, Oracle PGX, Amazon Neptune, etc.
- Different graph databases use different property graph models and formats
- We define the property graph (PG) data model and its serialization (PG and JSON-PG)
- We also provide several **converters** into various other related data formats

PG formats

2.1 PG format

- A PG file consists of lines that describe nodes and edges
- Each line describes one node or one edge

example.pg

```
# NODES
101 :person name:Alice country:"United States"
102 :person :student name:Bob country:Japan

# EDGES
101 -- 102 :same_school :same_class since:2012
101 -> 102 :likes since:2015
```

2.1.1 Nodes

```
<node_id> :<label1> :<label2> ... <key1>:<value1> <key2>:<value2> ...
```

- All elements are separated by space or tab
- Node IDs have to be unique
 - If there are multiple lines with the same Node ID, latter ones are ignored
- Each line can contain arbitrarily many labels
- Each line can contain arbitrarily many properties
- Each property can have multiple values.
 - The following example has multiple values as name property

```
101 :person name:Alice name:Ally country: "United States"
```

2.1.2 Edges

- · Basically, edge lines have the same format as node lines
- However, the first three columns contain source node ID, direction, and destination node ID
- An edge can be directed -> or undirected --
- The combinations of node IDs do NOT have to be unique. (= multiple edges are allowed)
 - An edge line will be ignored if a non-defined node ID is used

2.1.3 Data type

PG format allows the following data types:

- Integer: Written as a sequence of digits
 - For example, 1, 009 and 301
- Double-precision floating-point number (double): Written as a sequence of digits with exact one period
 - For example, 1.0, 2.321 and 001.002
- String: Anything else
 - Should be double quoted if it contains a space, tab, or colon (:)
 - To escape double quotes, use \"
 - For example, Alice, x2, "2.00", "United States" and "\"Quoted String\""

Each element can have one of the following data types:

- Node ID: integer or string
- · Label: string
- Property key: string
- Property value: integer, double, or string

2.2 JSON-PG format

JSON format is useful for being processed by web clients, while the PG (flat file) format above is convenient for users and file systems.

This format basically follows the rules of the general JSON format and our PG format, however:

- Nodes and edges are listed under nodes and edges elements, respectively
- Edge direction is defined with the boolean element undirected. By default it is false (= directed)
- Labels are listed under the labels element

• Properties (= key-value pairs) are listed under the properties element

example.json

2.3 Comparing the formats

PG

```
# NODES
101 :person name:Alice country:"United States"
102 :person :student name:Bob country:Japan

# EDGES
101 -- 102 :same_school :same_class since:2012
101 -> 102 :likes since:2015
```

JSON-PG

PG Tools

3.1 Installation

If **Docker** is installed on your machine, run the following:

```
$ alias pg2dot='docker run --rm -v $PWD:/work g2glab/pg:0.3.4 pg2dot'
$ pg2dot --version
0.3.4
```

Otherwise, install **Git** and **Node**, then run the following:

```
$ git clone -b vx.x.x https://github.com/g2glab/pg.git
$ cd pg
$ npm install
$ npm link
$ pg2dot --version
0.3.4
```

3.2 Quick start

Create some sample data:

```
$ vi data.pg
```

data.pg

```
p1 :person name:Bob
p2 :person name:Alice
p1 -> p2 :likes since:2013
p1 -- p2 :friend since:2011
```

Run the pg2dot command as an example:

```
$ pg2dot data.pg data "data.dot" has been created.
```

data.dot

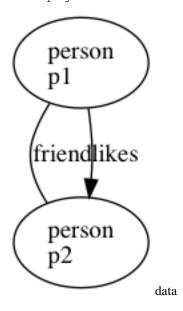

```
digraph "data" {
   "p1" [label="person\lp1\l" name="Bob"]
   "p2" [label="person\lp2\l" name="Alice"]
   "p1" -> "p2" [label="likes\l" since="2013"]
   "p1" -> "p2" [label="friend\l" since="2011" dir=none]
}
```

You can now generate a PNG image from the converted file using graphviz.

```
$ dot -T png data.dot -o data.png
```

data.png

8

3.3 PG Tools commands

```
$ pg2dot <input_pg_file> <output_path_prefix>
$ pg2pgx <input_pg_file> <output_path_prefix>
$ pg2neo <input_pg_file> <output_path_prefix>
$ pg2aws <input_pg_file> <output_path_prefix>
```

Loading to databases

4.1 Neo4j

4.1.1 Load With Docker

Create Neo4j container.

```
$ docker run -d \
-p 7474:7474 \
-p 7687:7687 \
--name neo4j \
--env NEO4J_AUTH=none \
neo4j
```

Copy Neo4j files to the container.

```
$ docker cp <path/to/edges/file> neo4j:/var/lib/neo4j/import/neo.edges
$ docker cp <path/to/nodes/file> neo4j:/var/lib/neo4j/import/neo.nodes
```

e.g.

```
$ docker cp output/musician/neo/*.edges neo4j:/var/lib/neo4j/import/neo.edges
$ docker cp output/musician/neo/*.nodes neo4j:/var/lib/neo4j/import/neo.nodes
```

Import data and reload Neo4j server.

```
docker exec neo4j bash -c \
"rm -rf data/databases/graph.db/ && neo4j-admin import \
   --database=graph.db \
   --nodes=import/neo.nodes \
   --relationships=import/neo.edges \
   --delimiter='\t' \
   && chown -R root:root /data" \
   && docker restart neo4j
```

Access to http://localhost:7474 on your web browser to see the imported data.

4.1.2 Load Without Docker

Create sample data.

```
$ vi data.pg
```

data.pg

```
p1 :person name:Bob
p2 :person name:Alice
p1 -> p2 :likes since:2013
p1 -- p2 :friend since:2011
```

Create Neo4j style nodes/edges files.

```
$ alias pg2neo='docker run --rm -v $PWD:/work g2glab/pg:x.x.x pg2neo'
$ pg2neo data.pg
```

Remove existing Neo4j database files.

```
$ rm -r $NEO4J_DIR/data/databases/graph.db
```

Import data from nodes/edges files.

```
$ $NEO4J_DIR/bin/neo4j-import \
  --into $NEO4J_DIR/data/databases/graph.db \
  --nodes output/data.neo.nodes \
  --relationships output/data.neo.edges
```

Start Neo4j console and access its browser (http://localhost:7474/browser/).

```
$ $NEO4J_DIR/bin/neo4j console
```

4.2 Oracle Labs PGX

Create sample data.

```
$ vi data.pg
```

data.pg

10

```
p1 :person name:Bob
p2 :person name:Alice
p1 -> p2 :likes since:2013
p1 -- p2 :friend since:2011
```

Create PGX style nodes/edges files.

```
$ alias pg2pgx='docker run --rm -v $PWD:/work g2glab/pg:x.x.x pg2pgx'
$ pg2pgx data.pg
```

Run PGX console and load the data.

```
$ $PGX_DIR/bin/pgx
pgx> G = session.readGraphWithProperties("data.pgx.json")
```

4.3 Amazon Neptune

Create sample data.

```
$ vi data.pg
```

data.pg

```
p1 :person name:Bob
p2 :person name:Alice
p1 -> p2 :likes since:2013
p1 -- p2 :friend since:2011
```

Create Neptune style nodes/edges files.

```
$ alias pg2aws='docker run --rm -v $PWD:/work g2glab/pg:latest pg2aws' $ pg2aws data.pg
```

Load the data.

```
$ curl -X POST \
-H 'Content-Type: application/json' \
http://<Neptune-Endpoint>.us-west-2.neptune.amazonaws.com:8182/loader -d'
{ "source" : "s3://<S3-Bucket-Name>/",
    "format" : "csv",
    "iamRoleArn" : "arn:aws:iam::<AWS-account-ID>:role/NeptuneLoadFromS3",
    "region" : "us-west-2",
    "failOnError" : "FALSE"
}'
```

After loading the data into Neptune you will receive a load-ID that can be used for checking your load status.

Output:

(continues on next page)

(continued from previous page)

```
"retryNumber" : 2,
    "status" : "LOAD_CANCELLED_DUE_TO_ERRORS",
    "totalTimeSpent" : 3,
    "startTime" : 1574269317,
    "totalRecords" : 10656,
    "totalDuplicates" : 0,
    "parsingErrors" : 8,
    "datatypeMismatchErrors" : 0,
    "insertErrors" : 0
}
```

Property Graph Exchange Format

https://arxiv.org/abs/1907.03936

5.1 Abstract

Recently, a variety of database implementations adopting the property graph model have emerged. However, interoperable management of graph data on these implementations is challenging due to the differences in data models and formats. Here, we redefine the property graph model incorporating the differences in the existing models and propose interoperable serialization formats for property graphs. The model is independent of specific implementations and provides a basis of interoperable management of property graph data. The proposed serialization is not only general but also intuitive, thus it is useful for creating and maintaining graph data. To demonstrate the practical use of our model and serialization, we implemented converters from our serialization into existing formats, which can then be loaded into various graph databases. This work provides a basis of an interoperable platform for creating, exchanging, and utilizing property graph data.

5.2 Introduction

Increasing amounts of scientific and social data are described and analyzed in the form of graphs. In the context of graph analysis, the **property graph model** is becoming popular; various graph database engines, including Neo4j, Oracle Labs PGX, and Amazon Neptune, adopt this model. These graph database engines support powerful algorithms for traversing or analyzing graphs. In contrast to the standardized RDF, however, property graphs lack a standardized data model.

Here, we considered the general requirements for representing property graphs and designed two serialization formats as flat text and JSON. These formats can be converted into specific formats for each of the databases mentioned above. The serialization formats independent of certain database implementations will increase the interoperability of graph databases and will make it easier for users to import accumulated graph data.

5.3 Model definition

Here, we define the property graph model independent of specific graph database implementations. For the purpose of interoperability, we incorporate differences in property graph models, taking into consideration multiple labels or property values for nodes and edges, as well as mixed graphs with both of directed and undirected edges. The property graph model we redefine here requires the following characteristics:

- A property graph contains nodes and edges.
- Each of the nodes and edges can have zero or more labels.
- Each of the nodes and edges can have properties (key-value pairs).
- Each property can have multiple values.
- Each edge can be directed or undirected.

More formally, we define the property graph model as follows.

Definition 1. Property Graph Model

(to be updated..)

5.4 Serialization

According to our definition of the property graph model, we propose serialization in flat text and JSON. The flat text format (PG) is better for human readability and line-oriented processing, while the JSON format (JSON-PG) is best used for server-client communication.

The flat text PG format has the following characteristics, and an example is given in **Figure 1**.

- Each line describes a node or an edge.
- All elements in each line are separated by space or tab.
- In each of the node lines, the first column contains the node ID.
- In each of the edge lines, the first three columns contain the source node ID, the direction, and the destination node ID.
- Each line can contain an arbitrary number of labels.
- Each line can contain an arbitrary number of properties (key-value pairs).

Figure 1. Example of PG

```
# NODES
101 :Person name:Alice age:15 country:"United States"
102 :Person :Student name:Bob country:Japan country:Germany

# EDGES
101 -- 102 :sameSchool :sameClass since:2012
102 -> 101 :likes since:2015
```

More formally, we describe the PG format in the EBNF notation as follows.

Definition 2. PG Format

EBNF notation of the PG format.

```
PG ::= (Node | Edge) +
Node ::= NODE_ID Labels Properties NEWLINE

Edge ::= NODE_ID Direction NODE_ID Labels Properties NEWLINE

Labels ::= Label*

Properties ::= Property*

Label ::= ':' STRING

Property ::= STRING ':' Value

Value ::= STRING | NUMBER

Direction ::= '--' | '->'
```

Next, we describe the JSON-PG format which follows the JSON syntax in addition to the above definition of the property graph model. The JSON-PG format has the following characteristics, and an example of the format is shown in **Figure 2**. It is to be noted that, whereas the set of labels or property values are represented as arrays in JSON, those elements are supposed to have no specific order according to the the property graph model.

- Nodes and edges are listed under nodes and edges elements, respectively.
- Edge direction is defined with the boolean element undirected. By default it is false (directed).
- Labels are listed under the labels element.
- Properties (key-value pairs) are listed under the properties element.

Figure 1. Example of PG-JSON

```
"nodes":[
  {
   "id":101,
   "labels":["Person"],
   "properties": {"name": ["Alice"], "age": [15], "country": ["United States"]}
  },
   "id":102,
   "labels":["Person", "Student"],
   "properties": { "name": ["Bob"], "country": ["Japan", "Germany"] }
  }
],
"edges":[
  {
   "from":101,
   "to":102,
   "undirected":true,
   "labels":["sameSchool", "sameClass"],
   "properties":{"since":[2012]}
  },
  {
   "from":102,
   "to":101,
   "labels":["likes"],
   "properties": { "since": [2015] }
  }
]
```

Furthermore, we have implemented command-line tools to convert between PG and JSON-PG, as well as to transform them into formats for well-known graph databases such as Neo4j, Oracle Labs PGX, and Amazon Neptune. The practical use cases of our tools demonstrate that the proposed data model and formats have the capability to describe property graph data begin used in existing graph databases (see https://github.com/g2glab/pg).

5.4. Serialization 15

5.5 Conclusion

In this work, we redefined the property graph model independent of specific graph database implementations and also proposed serialization formats based on the data model. Further, we implemented practical tools to convert our formats into existing ones. Our model and serialization will increase the interoperability of existing graph databases and make it easier for users to create, exchange, and utilize property graph data.
